PCR and standard library screening techniques were used to further analyse previously isolated slit cDNA clones. A cDNA clone representing the 5' most 2.4kb of sequence was isolated from a larval library and PCR was used to isolate a corresp. sequence from a 4-8 hour embryonic library. Two forms of the SLIT message were identified differing by 33 nucleotides. Genomic and cDNA sequencing indicates the transcripts consists of an approximately 314bp 5' untranslated leader sequence, followed by either-a 4407bp or 4440bp ORF depending on the splice form and a 4kb 3'.UTR.

                                                                   Claim 15; Page 82-91; 114pp; Japanese.

The present sequence encodes a polypeptide which suppresses proliferation and differentiation of undifferentiated cells such as neurons and blood cells. The polypeptide may be used for the prevention and control of disorders involving undifferentiated cells, such as leukaemia and malignant tumours, and improvement blood formation, e.g. after immunosuppression.
                                                                                                                                                                                                                                                                                                                                                                                                                                                         29-MAY-1997.

CDNA clones (140090 and 140091) respectively code for human Serrate-1 (W05833) and human Serrate-2 (W05833), ligands for Notch that are believed to play a major role in determining cell fates in the central nervous system. The clones were isolated from a foetal brain cDNA library using probes obtd. by PCR amplification of human placental cDNA with primers based on conserved sequences of brosophila Serrate and Delta. The CDNA can be incorporated into vectors and utilised in the treatment and diagnosis of disorders of

Principle Accordate protein, nucleic acid and antibodies - used in the study and manipulation of differentiation and other the study and manipulation of differentiation and other physiological processes a physiological processes a Claim 39; Pages 74-80; 119pp; English.

Two Drosophila ganomic phage libraries were screened and recombinant connes were isolated. The CDNAs in lambda 910 were isolated from an early pupal library. The Cl CDNA was isolated from an early pupal library. The Cl CDNA was isolated using the 5' 700 bp; cerminal fragment of the Cl CDNA as probe. The complete 556lbp sequence of DNAs (Q4340). The deduced protein was derived from Cl and C3 cDNAs (Q4340). The deduced protein product appears to be peptide; and S42-564 represent potential membrane associated region; as 1221-145 represent the putative transmembrane domain.

Disclosure; Page 89-94; 161pp; English.

2 cDNA clones (T40090 and T40091) respectively code for human Serrate-1 (W05833) and human Serrate-2 (W05833), ligands for Notch that are believed to play a major role in determining cell fates in the central nervous system. The clones were isolated from a foetal brain cDNA library using probes obtd. by PCR amplification of human placenta cDNA with primers based on conserved sequences of Drosophila Serrate and Delta. The cDNA can be incorporated into vectors and utilised in the treatment and diagnossis of disorders of cell fate and differentiation; antisense Serrate sequences can be used to treat malignancies of cell types that express Serrate or
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               T40090

                                                                                                                                                                                                                              Vertebrate Serrate protein and related DNA - used to treat or prevent malignancies characterised by increased Notch activity. Disclosure; Page 107-112; 161pp; English.

A cDNA clone (T40092) codes for chick Serrate (W05835), a ligand for Notch that is believed to play a major role in determining ce fates in the central nervous system. It was obtd. from an optic explant cDNA library using primers (see also T40094 and T40097) designed to recognise peptide motifs found in both Drosophila Del and Serrate proteins, and rescreening of the library using amplif clones. C-Serrate is expressed in the central nervous system, cranial placodes, nephric mesoderm, vascular system, and limb bud mesenchume
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   C-Serrate; Notch; cell differentiation; cell fate; tissue repair; central nervous system; cancer; therapy; diagnosis; ds.

Throducing random point mutations into nucleic acods - Introducing random point mutations into nucleic acods - Introducing random point mutation of molecules and screening.

The preparation, completion of molecules and screening.

The sclosure: p. English.

Random point mutations were introduced into the alpha fragment of E. Coli beta galactosidase. The wild type sequence was obtained as a single stranded template and an oligonucleotide was hybridised to it to generate a popn of DNA molecules which terminete at all possible nucleotide positions within a specified region. The variable 3' ends generated in this way are used as primers for reverse transcriptase. Nucleotides are misincorporated by the transcriptase and the molecules are emplated to forms that can be amplified and then expressed in a suitable host-vector system.

The sequence covers all 176 difft base substitutions, most of which see also P86575.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        81 vgccgymrttthhyrrmrbnvyrdynrsdaaawyccyrrsvkydccynachhddhyvybb 140

Oligonucleotide probe MK14-A consists of nucleotides 5-95 of MK14
(Q51735). It hybridized to all spp. of mycobacteria tested, but cross reacted to a few non-mycobacterial spp. The probe may be useful as an initial screen for mycobacterial infection.

Pred. No. is the number of results predicted by chance to have a score greater than or equal to the score of the result being printed, and is derived by analysis of the total score distribution.

Expression of the differentiation antigen F7D6 in tumorous tissues of Drosophila.

Bedian V; Jungklaus CE

Department of Biology, Clarkson University, Potsdam, New York 13676.

Dev Genet (UNITED STATES) 1987, 8 (3) p165-77, ISSN 0192-253X

Journal Code: DEG Languages: ENGLISH

Document type: JOURNAL ARTICLE

The 63-kDa antigen recognized by the monoclonal antibody F7D6 is present all Drosophila embryonic cells and disappears from most tissues as each one reaches its final, differentiated state. Larval tissues lose the antigen around the time of hatching, imaginal tissues lose it during metamorphosis, and germ cells lose it during gametogenesis (Bedian et al: Devel Biol 115:105-118, 1986). The nervous system and spontaneously contracting musculature of the gut and gonads are exceptions and remain antigen positive at all stages. The F7D6 antigen appears to be associated with dividing, undifferentiated cells and electrogenic cells. This prompted us to test tumors for antigen presence. We tested four different recessive mutants that give rise to four different types of tumorous transformation: the embryonic tumor Notch, several larval melanotic tumors, the imaginal disc tumor 1(2)gl, and three alleles of the ovarian tumor otu. In all cases, tumorous tissues in homozygotes contained the F7D6 antigen. The electrophoretic mobility of the antigen appeared to be unaltered in tumorous tissues compared to normal cells, but the antigen is expressed at higher levels. The antigen is found on the cytoplasmic surface of plasma membranes and appears to be a marker of undifferentiated normal and tumorous cells. Similarities and differences between the F7D6 antigen and Drosophila c-src protein are discussed.

[Adult T-cell leukemia (ATL)]

Takatsuki K

Kumamoto University Medical School.

Gan To Kagaku Ryoho (JAPAN) Apr 1989, 16 (4 Pt 2-1) p880-5, ISSN 0385-0684 Journal Code: 6T8

Languages: JAPANESE Summary Languages: ENGLISH Document type: JOURNAL ARTICLE English Abstract

Adult T-cell leukemia (ATL) was first discovered and reported in Japan, where it has a high incidence in the southwest region. The retrovirus HTLV-I (human T-cell lymphotropic virus type I) is considered to be related to its etiology. In ATL endemic areas, HTLV-I carriers are found at a fairly high percentage even among healthy individuals. ATL shows diverse clinical features. It can be divided into 5 types (acute type, chronic type, smoldering type, crisis type, and lymphoma type). ATL cells originate from the CD4-positive subset of peripheral T cells; they show a characteristic notch in the nucleus and a lobulation tendency. ATL resists chemotherapy, and patients with acute and lymphoma types have quite a poor

prognosis. A definite diagnosis of ATL is made by documenting the presence of HTLV-I proviral DNA in the DNA of tumor cells. HTLV-I infection is caused by transmission of live lymphocytes via three routes (from mother to children, from males to females, and by transfusion). Familial occurrence of ATL is frequently seen. HTLV-I infection is also seen in other countries, but its incidence is highest in Japan. It is thus an urgent task for Japanese physicians to eliminate HTLV-I infection.

C R Acad Sci III (FRANCE) Sep 1993, 316 (9) p1097-123, ISSN 0764-4469 Journal Code: CA1

Languages: ENGLISH, FRENCH

Document type: JOURNAL ARTICLE; REVIEW; REVIEW, TUTORIAL

The Notch gene of Drosophila plays an important role in cell fate specification throughout development. The Notch protein contains a large extracellular domain of 36 EGF-like repeats as well as 3 Notch/lin-12 repeats and an intracellular domain with 6 cdc10/ankyrin repeats, motifs which are highly conserved in several vertebrate Notch homologues [1-7]. In this review we summarize the results of two recent studies which attempt to establish structure-function relationships of the various domains of the Notch gene product [8, 9]. The functions of various structural domains of the Notch protein in vivo were investigated using a series of deletion mutants which have been ectopically expressed either under the hsp70 under the sevenless eye-specific promoter. heat-shock promoter orTruncation of the extracellular domain of Drosophila Notch produces an activated receptor as judged by its ability to cause phenotypes matching those of gain-of-function alleles or duplications of the Notch locus [8]. Equivalent truncations of vertebrate Notch-related proteins have been associated with malignant neoplasms and other developmental abnormalities 10, 11]. In contrast, dominant negative phenotypes result from overexpression of a protein lacking most intracellular sequences. These

results were extended by an analysis of activated Notch function at single-cell resolution in the Drosophila compound eye [9]. It was shown that while overexpression of full-length Notch in defined cell types has no apparent effects, overexpression of activated Notch in the same cells transiently blocks their proper cell-fate commitment, causing them to either adopt incorrect cell fates or to differentiate incompletely. Moreover, an activated Notch protein lacking the transmembrane domain is translocated to the nucleus, raising the possibility that Notch may participate directly in nuclear events. (68 Refs.)

Document type: JOURNAL ARTICLE; REVIEW; REVIEW, TUTORIAL

In this short review, we will give an overview of the various genes that can be activated by insertion of proviral DNA of the mouse mammary tumor virus during the formation of mammary cancer. These genes fall within three families: Wnt genes, FGF genes and Notch-related genes. We will summarize our current understanding of the roles of these genes in tumorigenesis and in normal development, and the mechanisms of action of their gene products. Finally, we will give some examples of cooperation between these genes in various biological settings. (91 Refs.)

The Notch gene of Drosophila encodes a large transmembrane protein involved in cell-cell interactions and cell fate decisions in the Drosophila embryo. To determine if a gene homologous to Drosophila Notch playis a role in early mouse development, we screened a mouse embryo cDNA library with probes from the Xenopus Notch homolog, Xotch. A partial cDNA clone encoding the mouse Notch homolg, which we have termed Motch, was used to analyze expression of the Motch gene. Motch transcripts were detected in a wide variety of adult tissues, which included derivatives of all three germ layers

The TLE genes are the human homologues of Drosophila groucho, a member of the Notch signaling pathway. This pathway controls a number of different cell-fate choices in invertebrates and vertebrates. We are interested in investigating the functions of the TLE gene family during epithelial determination and carcinogenesis. We show that expression of individual TLE genes correlates with immature epithelial cells that are progressing toward their terminally differentiated state, suggesting a role during epithelial differentiation. In both normal tissues and conditions resulting from incorrect or incomplete maturation events, such as metaplastic and neoplastic transformations, TLE expression is elevated and coincides with Notch expression, implicating these molecules in the maintenance of the undifferentiated state in epithelial cells. We also show that TLE1 and TLE2 are organized in a tandem array at chromosomal location 19p13.3, while TLE3 maps to 15q22.

Notch is a highly conserved transmembrane protein that is involved in fate decisions and is found in organisms ranging from Drosophila to cell humans. A human homologue of Notch, TAN1, was initially identified at the breakpoint chromosomal of a subset of T-cell lymphoblastic leukemias/lymphomas containing a t(7;9) chromosomal translocation; however, oncogenesis has been unclear. Using a bone marrow in reconstitution assay with cells containing retrovitally transduced TAN1 analyzed the oncogenic potential of both nuclear extranuclear forms of truncated TAN1 in hematopoietic cells. Although the Moloney leukemia virus long terminal repeat drives expression in most hematopoietic cell types, retroviruses encoding either form of the TAN1 protein induced clonal leukemias of exclusively immature T cell phenotypes in apprx 50% of transplanted animals. All tumors overexpressed truncated TAN1 of the size and subcellular localization predicted from the structure of the gene. These results show that TAN1 is an oncoprotein and suggest truncation that overexpression are important determinants of and transforming activity. Moreover, the murine tumors caused by TAN1 in the bone marrow transplant model are very similar to the TAN1-associated human tumors and suggest that TAN1 may be specifically oncotropic for T cells.

Translocation-associated Notch homologue (TAN-1), a gene originally cloned from the translocation breakpoint of a human T cell leukemia carrying a 9:7(q34.3) translocation, encodes a protein belonging to the Notch/Lin-12/Glp-1 receptor family. These receptors mediate the specification of numerous cell fates during development in invertebrates and vertebrates. The intracellular portion of Notch/TAN-1 contains six ankyrin repeats that are similar to those found in cytoplasmic I-kappa-B

proteins. I-kappa-B proteins are specific inhibitors of nuclear factor (NF)-kappa-B/Rel transcription factors. Here we show that TAN-1 has functional properties of an I-kappa-B-like regulator with specificity for the NF-kappa-B p50 subunit. A recombinant polypeptide corresponding to the cytoplasmic portion of TAN-1 (TAN-1-C) specifically inhibited the DNA binding of p50-containing NF-kappa-B complexes. When overexpressed in an appropriate cell line, TAN-1-C prevented kappa-B-dependent transactivation in transient reporter gene assays in a fashion similar to the structurally related protein, Bcl-3. TAN-1-C could activate kappa-B-dependent gene expression by attenuating the inhibitory effect of an excess of p50 homodimers. Immunoprecipitation experiments showed that the TAN-1 from a T cell line is associated with NF-kappa-B containing p50 and p65 subunits. These observations indicate that TAN-1-C may directly engage NF-kappa-B transcription factors and modulate nuclear gene expression.

The development of cancer is a cellular process that reflects and is partly driven by alterations in cell determination. Mutations in various molecules responsible for cell determination have been identified as being oncogenic, but little is known about the involvement of normal cell fate-determining mechanisms in the oncogenic process. The Notch pathway defines an evolutionarily conserved, general cell interaction mechanism that controls fundamental aspects of cell determination during vertebrate and invertebrate development. We have explored the involvement of the human Notch pathway in human cervical tissues, which define a cellular environment where cell fate changes take place and where neoplastic conditions have been well characterized. Our evidence suggests that Notch expression is associated with cell populations that are undergoing cell

fate changes and that Notch activity can be used to monitor cell fate abnormalities in cervical as well as other epithelial neoplasias.

Drosophila, over 50 genes have been identified in which loss-of-function mutations lead to excess cell proliferation in the embryo, in the central nervous system, imaginal discs or hematopoietic organs of the larva, or in the adult gonads. Twenty-two of these genes have been cloned and characterized at the molecular level, and nine of them show clear homology to mammalian genes. Most of these mammalian genes had not been previously implicated in cell proliferation control. Overgrowth in some of the mutants involves conversion to a cell type that, in normal development, shows more cell proliferation than the original cell type. Thus the neurogenic mutants, including Notch, show conversion of epidermal cells to neuroblasts, leading to the 'neurogenic' phenotype of excess nervous tissue. The ovarian tumor mutants show conversion of the female germ line to a cell type resembling the male germ line, which undergoes more proliferation than the female germ line. Mutations of the fat locus cause hyperplastic overgrowth of imaginal discs, in which the epithelial structure is largely intact. The predicted fat protein product is a giant relative of cadherins, supporting indications from human cancer that cadherins play an important role in tumor suppression. Mutations in the lethal(2)giant larvae and lethal(1)discs large genes cause neoplastic overgrowth of imaginal discs as well as the larval brain. The dig gene encodes a membrane-associated quanylate kinase homolog that is localized at septate junctions between epithelial cells. This protein is a member of a family of homologs that also includes two proteins found at mammalian tight junctions (ZO-1 and ZO-2) and a protein found at mammalian synaptic junctions (PSD-95/SAP90). Genes in which mutations cause blood cell overproduction include aberrant immune response-8, which encodes the RpS6 ribosomal protein and hopscotch, which encodes a putative non-receptor protein tyrosine kinase. The gene products identified by ovarian tumor mutants do not show clear amino acid sequence homology to known proteins. Drosophila provides an opportunity to rapidly identify and characterize tumor suppressor genes, many of which have mammalian homologs that might also be involved in cell proliferation control and tumor suppression.

In Drosophila the Notch gene controls differentiation to various cell fates in many tissues. Three mammalian Notch homologs have recently been identified: Notch 1, 2, and 3. All three homologs are very highly conserved relative to the Drosophila Notch gene, which suggests that they are important for cell differentiation in mammals. This notion is supported by the previous finding of a truncated, translocated form of the human NOTCH1 gene (formerly TAN1) in three cases of leukemia. Given this genetic link between NOTCH1 and tumor formation, it is of interest to establish the chromosomal positions of the other two homologs. We report the identification of cosmid clones for the human NOTCH1, 2, and 3 genes. These clones were used as probes in fluorescence in situ hybridization to human metaphase chromosomes, and the results, combined with data from somatic cell hybrid panels, show that the NOTCH2 and 3 genes are located at positions 1p13-p11 and 19p13.2-p13.1, respectively, which are regions of neoplasia-associated translocation.

P19 cells, a mouse embryonal carcinoma line, can be induced to differentiate into neurons. After induction, however, only a small subpopulation of cells develop as neurons, suggesting that equipotent cells adopt different cell fates. In invertebrate systems, the lin-12-Notch family of genes is thought to control the choice of cell fate. We have therefore asked whether activation of murine Notch (mNotch) regulates neuronal differentiation in P19 cells. We demonstrate that a dominant gain-of-function mutant of mNotch suppresses neurogenesis, as well as myogenesis in P19 cells. Overexpression of the full-length mNotch protein also suppresses neurogenesis. In contrast, the differentiation of glia is not affected by an activated mNotch homologue. These data indicate that mNotch may play a central role in the choice of cell fate in differentiating cells in culture and suggests that mNotch may play a similar role in the choice of fate in the developing mammalian embryo.

Members of the Notch gene family have been shown to mediate cell-fate decisions by multipotent precursors in a number of different systems. To determine whether members of this family might play a similar role in hematopoiesis, we asked if homologues of the Notch gene are expressed in hematopoietic precursors. Using degenerate oligonucleotides corresponding to conserved amino acid sequences in known Notch homologues as primers for the polymerase chain reaction (PCR), we demonstrated that at least one Notch homologue is expressed in human bone marrow CD34+ cells, a population enriched for hematopoietic precursors. Cloning and sequencing of the PCR products identified this Notch homologue as TAN-1, a member of the Notch family previously cloned from a T-cell leukemia with a translocation involving this gene. Subsequent evaluation of bone marrow hematopoietic cells for TAN-1 expression using a reverse transcription-PCR assay confirmed the expression of TAN-1 in CD34+ hematopoietic precursors, including the immature subset that lacks expression of lineage-associated antigens (CD34+lin-). These findings, together with the known role of Notch homologues in other systems, suggest that members of the Notch family, included TAN-1, may be involved in mediating cell-fate decisions during hemotopoiesis.

Expression of the int-3 locus is activated in mouse mammary tumors as a consequence of insertional mutagenesis by the mouse mammary tumor virus (MMTV). Integration of the MMTV provirus into the into-3 locus promotes the transcription and translation of flanking cellular int-3 sequences sharing significant homology with the intracellular domain of the nuerogenic Notch gene of Drosophila, and with the yeast cell cycle regulatory genes cdc10 and SW16. To determine the in vivo consequences of activated int-3 expression, transgenic mice were generated harboring a genomic tumor DNA

fragment consisting of the MMTV LTR and the flanking cellular int-3 sequences. All six int-3 founder transgenic mice and the progeny of one established line exhibited similar dramatic phenotypic abnormalities in tissues in which the transgene was expressed. Focal and often multiple poorly differentiated mammary and salivary adenocarcinomas appeared in the majority of transgenic mice between 2 and 7 months of age. Significantly, mammary glands were arrested in development and were lactation deficient in all female int-3 mice. The salivary glands, glands of the nasal mucosa and maxillary sinus, the extraorbital lacrimal glands, and the Harderian glands of juvenile and adult transgenic mice all contained proliferating immature ductule cells and were incompletely differentiated. In addition, all male int-3 transgenic mice were sterile, apparently the result of severe hyperplasia of the epididmyis. These findings demonstrate in vivo that expression of the activated Notch-related int-3 gene causes deregulation of developmental controls and hyperproliferation of glandular epithelia.

Previously we described joining of DNA in the .beta. T cell receptor gene to DNA of an uncharacterized locus in a $t(7;9)\,(q34;q34.3)$ chromosomal translocation from a case of human lymphoblastic leukemia (T-ALL). We now show that the locus on chromosome 9 contains a gene highly homologous to the Drosophila gene Notch. Transcripts of the human gene, for which we propose the name TAN-1, and its murine counterpart are present in many normal human fetal and adult mouse tissues, but are most abundant in lymphoid tissues. In $t(7;9)\,(q34;q34.3)$ translocations from three cases of T-ALL, the breakpoints occur within 100 bp of an intron in TAN-1, resulting in truncation of TAN-1 transcripts. These observations suggest that TAN-1 may be important for normal lymphocyte function and that alteration of TAN-1 may play a role in the pathogenesis of some T cell neoplasms.

Division of Monoclonal Antibodies, Federal Drug Administration, Ctr. for Biologics Evaluation/Res., 8800 Rockville Pike, Bethesda, MD 20892 USA Journal of Experimental Medicine (USA), 1996, 183/5 (2025-2032) CODEN: JEMEA ISSN: 0022-1007

LANGUAGES: English SUMMARY LANGUAGES: English

Translocation-associated Notch homologue (TAN-1), a gene originally cloned from the translocation breakpoint of a human T cell leukemia carrying a 9:7(q34.3) translocation, encodes a protein belonging to the Notch/Lin- 12/Glp-1 receptor family. These receptors mediate the specification of numerous cull fates during development in invertebrates and vertebrates. The intracellular portion of Notch/TAN-1 contains six ankyrin repeats that are similar to those found in cytoplasmic IkappaB proteins. IkappaB proteins are specific inhibitors of nuclear factor (NF)-kappaB/Rel transcription factors. Here we show that TAN-1 has functional properties of an IkappaB-like regulator with specificity for the NF-kappaB p50 subunit. A recombinant polypeptide corresponding to the cytoplasmic portion of TAN-1 (TAN-1(C)) specifically inhibited the DNA binding of p50-containing NF-kappaB complexes. When overexpressed in an appropriate cell line, TAN-1(C) prevented kappaB-dependent transactivation in transient reporter gene assays in a fashion similar to the structurally related protein, Bcl-3. TAN-1(C) could activate kappaB-dependent gene expression by attenuating the inhibitory effect of an excess of p50 homodimers. Immunoprecipitation experiments showed that the TAN-1 from a T cell line is associated with NF-kappaB containing p50 and p65 subunits. These observations indicate that TAN-1(C) may directly engage NF-kappaB transcription factors and modulate nuclear gene expression. ?LOGOFF
